Lecce, Italy, September 2012

I. Conceptual Introduction to Atmospheric Planetary Boundary Layers

Evgeni Fedorovich

University of Oklahoma, School of Meteorology

Outline

- **Place and role of planetary atmospheric boundary layer (ABL) in Earth's atmosphere;**
- **Effects of temperature/density stratification in the ABL;**
- **Diurnal cycle of the ABL;**
- **Structure of convective, neutral, and stably stratified (stable) ABLs;**
- **Interactions of ABL with underlying surfaces;**
- **Interactions between ABL and free atmosphere.**

Place of planetary **ABL** in Earth's atmosphere

Planetary ABL flows

conflate four major **nasty** features of geophysical flows:

(i) turbulence,

(ii) density stratification,

(iii) rotation,

(iv) thermal forcing.

Effect of stratification in atmosphere

Wallace and Hobbs (2006)

(a)

(b)

$$\Gamma = -dT_e / dZ \text{ (normally } > 0) \text{ and } \Gamma_d = -(dT / dZ)_{\text{adiab}} = g / c_p$$

$$d\Theta_e / dZ \approx dT_e / dZ + \Gamma_d = -\Gamma + \Gamma_d$$

$$d\Theta_e / dZ > 0 \text{ **stable**}$$

$$d\Theta_e / dZ < 0 \text{ **unstable**}$$

Heat exchange in ABL flows

ABL stability parameters

Convenient variable to account for combined effect of heat and moisture on static stability is **buoyancy**

$$b = g(\theta_v - \theta_{vr}) / \theta_c,$$

where $\theta_v \approx \theta + 0.61\theta_c q$ is the **virtual potential temperature**.

(Turbulent vertical kinematic) **buoyancy flux** is $\overline{w'b'}$.

Commonly used **stability parameters**:

$\zeta = z/L$, where $L = -\frac{\overline{(-u'w')^{3/2}}}{\kappa \overline{w'b'}}$ is **Obukhov length (scale)**.

Flux Ri number $\text{Ri}_f = \frac{\overline{w'b'}}{u'w'(\partial\bar{u}/\partial z)}$, **gradient Ri number** $\text{Ri} = \frac{\partial\bar{b}/\partial z}{(\partial\bar{u}/\partial z)^2}$

represent ratio of buoyancy to shear turbulence production rates.

$$\frac{\text{Ri}}{\text{Ri}_f} = \text{Pr}_t = \frac{\varphi_h}{\varphi_m},$$

$$\text{Ri} = \frac{\text{Pr}_t}{\varphi_m} \zeta,$$

$$\text{Ri}_f = \frac{\zeta}{\varphi_m} = \frac{\text{Pr}_t}{\varphi_h} \zeta.$$

Daytime convective boundary layer (CBL)

In its dry version: a turbulent boundary layer primarily driven by heating from below with a secondary wind-shear forcing

after John Wyngaard

Potential temperature field in the inversion-capped CBL (DNS visualization)

CBL without wind shear

CBL with wind shear

Conventional nocturnal **stable** ABL (SBL)

after John Wyngaard

after Roland Stull

Surface energy balance components

Sensible heat flux:

$$F_H = \rho c_p \overline{w' \theta'} \equiv \rho c_p Q_z.$$

Latent heat flux:

$$F_L = L_v E = L_v \rho \overline{w' q'} \equiv L_v \rho D_z.$$

Approximate form of surface (s) energy budget:

$$F^* = F_{Hs} + F_{Es} + F_{Gs}.$$

F^* - surface net radiative flux; F_G - ground heat flux.

Surface energy balance

Energy balance

$$F^* = F_{Hs} + F_{Es} + F_{Gs}$$

Radiation balance

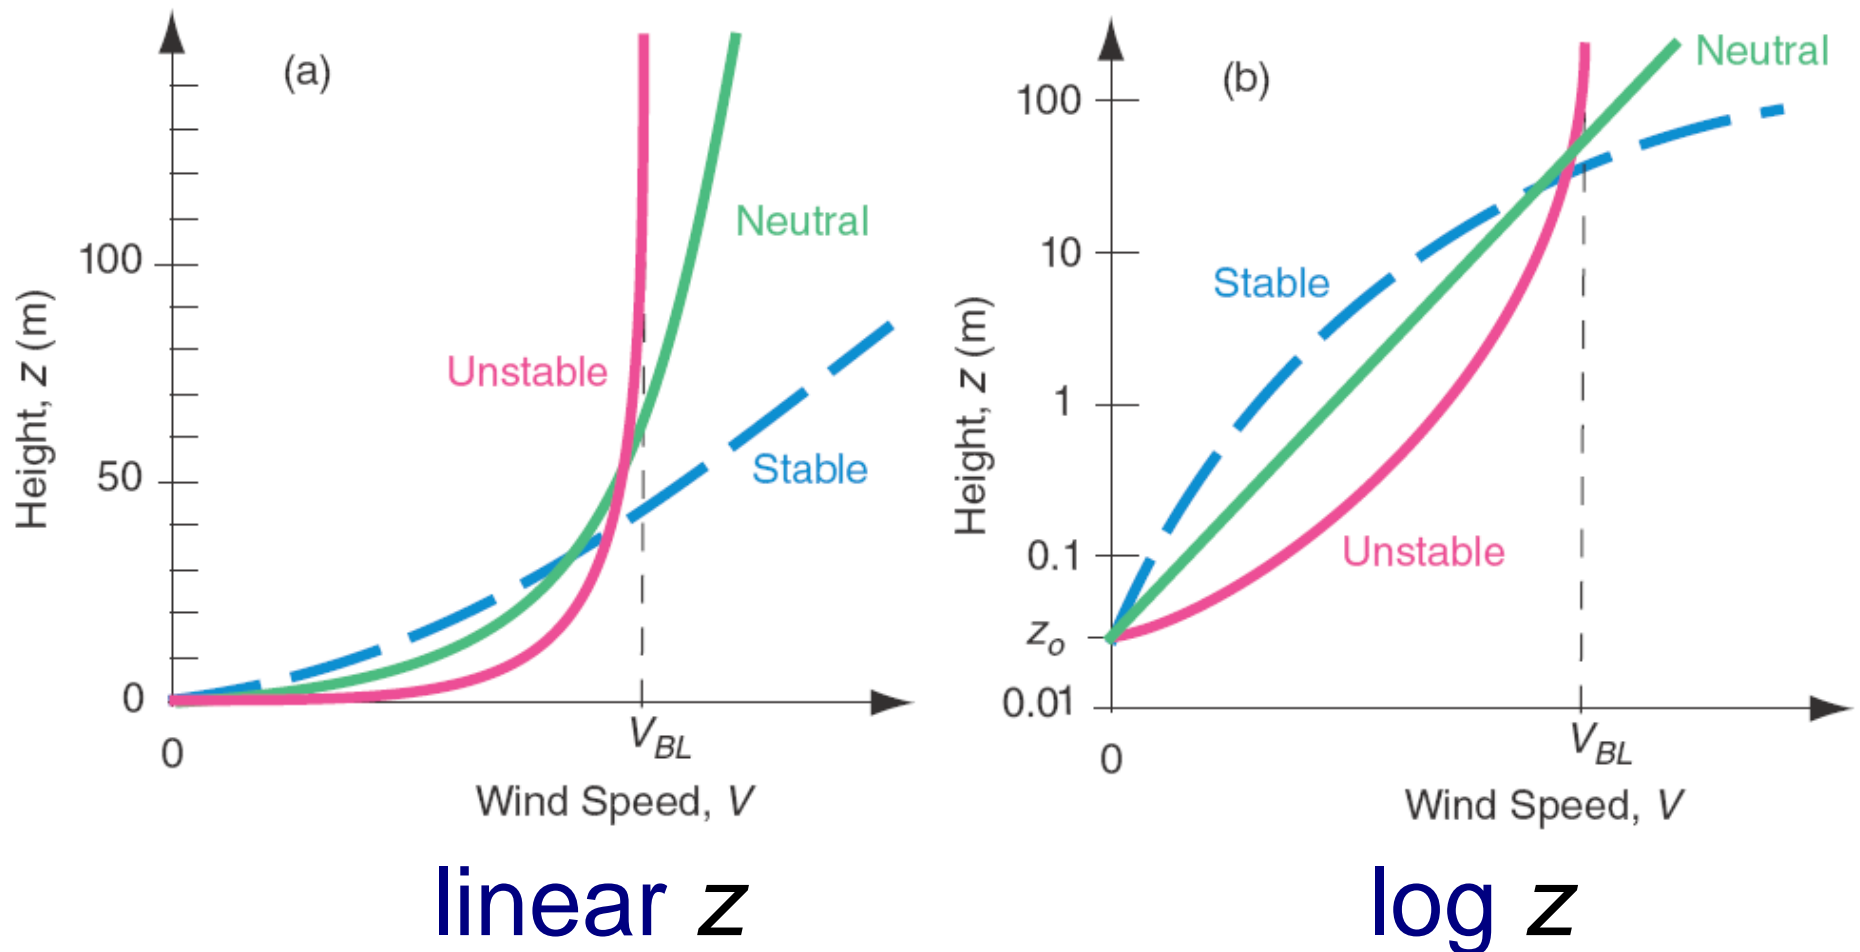

$$F_s^\downarrow - F_s^\uparrow + F_L^\downarrow - F_L^\uparrow = F^*$$
